                    Definitions of Managed Objects
               for Frame Relay Service Level Definitions

Status of this Memo

   This document specifies an Internet standards track protocol for the
   Internet community, and requests discussion and suggestions for
   improvements. Please refer to the current edition of the "Internet
   Official Protocol Standards" (STD 1) for the standardization state
   and status of this protocol. Distribution of this memo is unlimited.

Copyright Notice

Abstract

   This memo defines an extension of the Management Information Base
   (MIB) for use with network management protocols in TCP/IP-based
   internets. In particular, it defines objects for managing the Frame
   Relay Service Level Definitions.

Table of Contents

1. The SNMP Management Framework

    The SNMP Management Framework presently consists of five major
    components:

    o   An overall architecture, described in RFC 2571 [1].

    o   Mechanisms for describing and naming objects and events for the
        purpose of management. The first version of this Structure of
        Management Information (SMI) is called SMIv1 and described in STD
        16, RFC 1155 [2], STD 16, RFC 1212 [3] and RFC 1215 [4]. The
        second version, called SMIv2, is described in STD 58, RFC 2578
        [5], RFC 2579 [6] and RFC 2580 [7].

    o   Message protocols for transferring management information. The
        first version of the SNMP message protocol is called SNMPv1 and
        described in STD 15, RFC 1157 [8]. A second version of the SNMP
        message protocol, which is not an Internet standards track
        protocol, is called SNMPv2c and described in RFC 1901 [9] and RFC

1906 [10]. The third version of the message protocol is called
SNMPv3 and described in RFC 1906 [10], RFC 2572 [11] and RFC 2574
[12].

o Protocol operations for accessing management information. The
   first set of protocol operations and associated PDU formats is
   described in STD 15, RFC 1157 [8]. A second set of protocol
   operations and associated PDU formats is described in RFC 1905
   [13].

o A set of fundamental applications described in RFC 2573 [14] and
   the view-based access control mechanism described in RFC 2575
   [15].

A more detailed introduction to the current SNMP Management Framework
can be found in RFC 2570 [16].

Managed objects are accessed via a virtual information store, termed
the Management Information Base or MIB. Objects in the MIB are
defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIv2. A
MIB conforming to the SMIv1 can be produced through the appropriate
translations. The resulting translated MIB must be semantically
equivalent, except where objects or events are omitted because no
translation is possible (use of Counter64). Some machine readable
information in SMIv2 will be converted into textual descriptions in
SMIv1 during the translation process. However, this loss of machine
readable information is not considered to change the semantics of the
MIB.

2. Conventions

The keywords MUST, MUST NOT, REQUIRED, SHALL, SHALL NOT, SHOULD,
SHOULD NOT, RECOMMENDED, NOT RECOMMENDED, MAY, and OPTIONAL, when
they appear in this document, are to be interpreted as described in
RFC 2119 [22].

3. Overview

This MIB module addresses the items required to manage the Frame
Relay Forum's Implementation Agreement for Service Level Definitions
(FRF.13 [17]). At present, this applies to these values of the
ifType variable in the Internet-standard MIB:

o frameRelay (32)

o frameRelayService (44)

This section provides an overview and background of how to use this MIB module.

3.1. Frame Relay Service Level Definitions

The frame relay service level definitions address specific characteristics of a frame relay service that can be used to facilitate the following tasks:

o Evaluation of frame relay service providers, offerings or products.

o Measurement of Quality of Service.

o Enforcement of Service Level Agreements.

o Planning or describing a frame relay network.

The following parameters are defined in FRF.13 [17] as a sufficient set of values to accomplish the tasks previously stated.

o Delay - The amount of time elapsed, in microseconds, from the time a frame exits the source to the time it reaches the destination. NOTE: FRF.13 [17] defines this value in terms of milliseconds.

o Frame Delivery Ratio - The ratio of the number of frames delivered to the destination versus the number of frames sent by the source. This ratio can be further divided by inspecting either only the frames within the CIR or only the frames in excess of the CIR.

o Data Delivery Ratio - The ratio of the amount of data delivered to the destination versus the amount of data sent by the source. This ratio can be further divided by inspecting either only the data within the CIR or only the data in excess of the CIR.

o Service Availability - The amount of time the frame relay service was not available. There are three types of availability statistics defined in FRF.13 [17]: Mean Time to Repair, Virtual Connection Availability, and Mean Time Between Service Outages. The later two require information about the scheduled outage time. It is assumed that scheduled outage time information will be maintained by the network management software, so it is not included in the MIB module.

Consult FRF.13 [17] for more details.

3.2. Terminology

    o CIR - The Committed Information Rate (CIR) is the subscriber data
       rate (expressed in bits/second) that the network commits to
       deliver under normal network conditions [18].

    o DLCI - Data Link Connection Identifier [18].

    o Logical Port - This term is used to model the Frame Relay
       "interface" on a device [18].

    o NNI - Network to Network Interface [18].

    o Permanent Virtual Connection (PVC) - A virtual connection that has
       its end-points and bearer capabilities defined at subscription
       time [18].

    o Reference Point (RP) - The point of reference within the network
       model at which the calculations or data collection takes place.

    o UNI - User to Network Interface [18].

3.3. Network Model

   The basic model, as illustrated in figure 1 below, contains two frame
   relay DTE endpoints connected to a network cloud via a frame relay
   UNI interface. The network cloud can contain zero or more internal
   frame relay NNI connections that interconnect multiple networks. The
   calculations and data collection can be performed at any reference
   point within the network.

```
    +-------------+                                +-------------+
    | Frame Relay |                                | Frame Relay |
    | DTE Device  |                                | DTE Device  |
    +------+------+                                +------+------+
           |                                              |
          UNI                                            UNI
       Connection                                     Connection
           |                                              |
    +------+------+    NNI      +-------------+    NNI    +------+------+
    | Network A  +------------+  Network B  +------------+ Network C  |
    +-------------+ Connection +-------------+ Connection +-------------+
```

                             Figure 1
                  Frame Relay Network Reference Model

3.4. Reference Points

   The collection and calculations of the service level definitions
   apply to two reference points within the network. These two points
   are the locations where the frames are referenced in the collection
   of the service level specific information. The reference points used
   in the MIB module are shown in figure 2 below. For completeness, the
   module also allows for proprietary reference points which MAY exist
   anywhere in the network that is not a previously defined reference
   point. The meaning of the proprietary reference points is
   insignificant unless defined by the device manufacturer.

```
      +-------------------------+
      |+----------+ +----------+|
      ||          | |Measurement||
      ||Frame Relay---Engine     --(Source RP)----+
      ||DTE       | |(If Exists)||                |
      |+----------+ +----------+|                 |
      +-------------------------+                 |
        Frame Relay Source                        |

      |+----------+ +----------+|      |          |
      ||          | |Measurement||     |          |
      ||Frame Relay---Engine     --(Destination RP)--+
      ||DTE       | |(If Exists)||
      |+----------+ +----------+|
      +-------------------------+
```

   Figure 2
                  Reference Points (FRF.13 [17])

The MIB variables frsldPvcCtrlTransmitRP and frsldPvcCtrlReceiveRP
allow the user to view and configure the reference points at which
the calculations occur. These variables are specific to the device
on which they are located. Frame relay devices act as both frame
sources and frame destinations. The definitions in this MIB module
apply to the interaction of a pair of devices on the network path.
The same device can potentially use different reference points for
calculation and collection of the statistics based on whether the
referenced frame is sent or received by the device. When the device
is acting as a frame source, the value of frsldPvcCtrlTransmitRP
reflects the reference point used for all source calculations
pertaining to the specified PVC. When the device is acting as a
frame destination, the value of frsldPvcCtrlReceiveRP reflects the
reference point used for all destination calculations pertaining to
the specified PVC.

For example, FRF.13 [17] defines an Edge-to-Edge Egress Queue
measurement domain as a domain in which measurement is performed
between an Ingress Reference Point and an Egress Queue Input
Reference Point. For this domain between a source device and a
destination device, the value of frsldPvcCtrlTransmitRP for the
source device would be set to ingTxLocalRP(2) and the value of
frsldPvcCtrlReceiveRP for the destination device would be set to
eqiRxLocalRP(4). While it is usually the case that the reference
points would be equivalent on the remote device when monitoring
frames going in the opposite direction, there is no requirement for
them to be so.

It can be seen from the above example that a total of four reference
points are required in order to collect information for both
directions of traffic flow. The reference points represent the
transmit and receive directions at both ends of a PVC. If a device
has knowledge of the information from the remote device, it is
possible to collect the statistics from a single device. This is not
always the case. In most instances, two devices will need to be
monitored to capture a complete description of the service level on a
PVC. The reference points a single device is capable of monitoring
are contained in the frsldRPCaps object.

3.5. Measurement Methodology

This document neither recommends nor suggests a method of
implementation. This is left to the device manufacturer and should
be independent of the data that is actually collected.

Periodic collection of this data can be performed through either
polling of the data table, use of the sample tables or use of the
user history group of RFC 2021 [19].

3.6. Theory of Operation

   The following sections describe how to use this MIB module. They
   include row handling, data collection and data calculation. The
   recommendations here in are suggestions as to implementation and do
   not infer that they are the only method that can be used to perform
   such operations.

3.6.1. Capabilities Discovery

   Three objects are provided specifically to aid the network manager in
   discovering the capabilities of the device with respect to this MIB
   module.

   o frsldPvcCtrlWriteCaps   This object reports the write capabilities
                              of the PVC Control Table. Use this object
                              to determine which objects can be modified.
                              This need only be referenced if row
                              creation or modification is to be
                              performed.

   o frsldSmplCtrlWriteCaps This object reports the write capabilities
                              of the Sample Control Table. Use this
                              object to determine which objects can be
                              modified. The group need only be
                              referenced if the sample tables will be
                              used to collect historical information.

   o frsldRPCaps   This object reports the reference points at
                              which the device is capable of collecting
                              information. This object needs to be
                              referenced if row creation is to be
                              performed in the PVC Control Table.
                              Devices can only create rows containing
                              supported reference points.

   These objects do not imply that there is no need for an Agent
   Capabilities macro for devices that do not fully support every object
   in this MIB module. They are provided specifically to aid in the
   ensured network management operations of this MIB module with respect
   to row creation and modification.

   An additional four objects are provided to report and control memory
   the utilization of this MIB module. These objects are
   frsldMaxPvcCtrls, frsldNumPvcCtrls, frsldMaxSmplCtrls are
   frsldNumSmplCtrls. Together, they allow a manager to control the

amount of memory allocated for specific utilization by this MIB
module. This is done by setting the maximum allowed allocation of
controls.

3.6.2. Determining Reference Points for Row Creation

The performance of a PVC is monitored by evaluating the uni-
directional flow of frames from an ingress point to an egress point.
Reference points describe where each of the two measurements are
made. Monitoring both of the uni-directional flows that make-up the
PVC frame traffic requires a total of four reference points as shown
in Figures 3 through 5. A monitoring point that evaluates traffic is
restricted to counting frames that pass the reference points hosted
locally on the monitoring point. Thus, if the monitoring point is
near the ingress point of the flow, it will count the frames entering
into the frame relay network. The complete picture of frame loss for
the uni-directional flow requires information from the downstream
reference point located at another (remote) monitoring point.

The local monitoring point MAY be implemented in such way that the
information from the downstream monitoring point is moved to the
local monitoring point using implementation-specific mechanisms. In
this case all information required to calculate frame loss becomes
available from the local measurement point. The local measurement
point agent is capable of reporting all the objects in the
FrsldPvcDataEntry row - the counts for offered frames entering the
network and delivered frames exiting the network.

Alternatively, the local monitoring point MAY be restricted to counts
of frames observed on the local device only. In this case, the
objects of the FrsldPvcDataEntry row reporting what happened on the
remote device are not available.

The following list shows the possible valid reference points for an
FRF.13 SLA from the source reference point to the destination
reference point in both directions.

o Local Information Only

       Local Device: srcLocalRP, desLocalRP
       Remote Device: srcLocalRP, desLocalRP

o Remote Information Only

       Local Device: srcRemoteRP, desRemoteRP
       Remote Device: srcRemoteRP, desRemoteRP

    o Mixed Two Device Model 1 (Local Device Always Transmitter)

          Local Device: srcLocalRP, desRemoteRP
          Remote Device: srcLocalRP, desRemoteRP

    o Mixed Two Device Model 2 (Local Device Always Receiver)

          Local Device: srcRemoteRP, desLocalRP
          Remote Device: srcRemoteRP, desLocalRP

    o Mixed One Device Model 1 (Directional Rows)

          First Row: srcRemoteRP, desLocalRP (Receiver Row)
          Second Row: srcLocalRP, desRemoteRP (Sender Row)

    o Mixed One Device Model 2 (Device Based Rows)

          First Row: srcLocalRP, desLocalRP (Local Row)
          Second Row: srcRemoteRP, desRemoteRP (Remote Row)

   Each of the above combinations is valid and provides the same
   information.

   The following steps are recommended to find which reference points
   need to be configured:

   1) Locate both of the devices at either end of the PVC to be
      monitored.

   2) Determine the capabilities by referencing the frsldRPCaps object
      of each device.

   3) Locate the best combination of the two devices such that the
      necessary reference points are all represented.

   4) If any one of the necessary reference points does not exist in the
      combination of the two devices, it is not possible to monitor the
      FRF.13 defined SLA between the two reference point on the PVC.
3.6.2.1. Graphical Examples of Reference Points

   FRF.13 [17] defines three specific combinations of reference points:
   Edge-to-Edge Interface, Edge-to-Edge Egress Queue and End-to-End.

   Examples of valid reference points that may be used for each of these
   are discussed in the sections below.

It is often the case that a device knows as a minimum either only
local information or both local and remote information. Because
these are two common examples, each will be illustrated below.

3.6.2.1.1. Edge-to-Edge Interface Reference Point Example

```
               Device 1                            Device 2
          +------------+                      +------------+
          |   Ingress  |                      |   Egress   |
          |   +-----+  |                      |   +-----+  |
          |(A)|     |  |     Traffic Flow     |   |     |(B)|
        -->-->--     -->-->-->-->-->-->-->-->-->-->-     -->-->-->
          |   |     |  |   From Device 1 to 2 |   |     |  |
          |   +-----+  |                      |   +-----+  |
          |            |                      |            |
          |   Egress   |                      |   Ingress  |
          |   +-----+  |                      |   +-----+  |
          |(D)|     |  |     Traffic Flow     |   |     |(C)|
        <--<--<-     -<--<--<--<--<--<--<--<--<--<--     --<--<--
          |   |     |  |   From Device 2 to 1 |   |     |  |
          |   +-----+  |                      |   +-----+  |
          +------------+                      +------------+
```

              where (A), (B), (C) and (D) are reference points

                              Figure 3

   For devices with only local knowledge, one row is required on each
   device as follows:

   (A) frsldPvcCtrlTransmitRP for Device 1 = ingTxLocalRP(2)

   (B) frsldPvcCtlrReceiveRP for Device 2 = eqoRxLocalRP(5)

   (C) frsldPvcCtrlTransmitRP for Device 2 = ingTxLocalRP(2)

   (D) frsldPvcCtlrReceiveRP for Device 1 = eqoRxLocalRP(5)

   In which a single row is created on Device 1 containing reference
   points (A) and (D), and a single row is created on Device 2
   containing reference points (C) and (B).

   For devices with both local and remote knowledge, the two rows can
   exist in any combination on either device. For this example, the
   transmitting devices will be responsible for information regarding
   the flow for which they are the origin. Only one row is required per
   device for this example.

   (A) frsldPvcCtrlTransmitRP for Device 1 = ingTxLocalRP(2)

   (B) frsldPvcCtlrReceiveRP for Device 1 = eqoRxRemoteRP(11)

   (C) frsldPvcCtrlTransmitRP for Device 2 = ingTxLocalRP(2)

   (D) frsldPvcCtlrReceiveRP for Device 2 = eqoRxRemoteRP(11)

3.6.2.1.2. Edge-to-Edge Egress Queue Reference Point Example

```
              Device 1                                 Device 2
        +------------+                           +------------+
        |  Ingress   |                           |  Egress    |
        | +-----+    |                           | +-----+    |
        |(A)|    |   |      Traffic Flow         |(B)|    |   |
      -->-->--    --->-->-->-->-->-->-->-->-->--    -->-->-->
        |  |    |   |   From Device 1 to 2       |  |    |   |
        |  +-----+   |                           |  +-----+   |
        |            |                           |            |
        |  Egress    |                           |  Ingress   |
        | +-----+    |                           | +-----+    |
        |  |    |(D)|      Traffic Flow          |  |    |(C)|
      <--<--<-    -<--<--<--<--<--<--<--<--<--<--    --<--<--
        |  |    |   |   From Device 2 to 1       |  |    |   |
        |  +-----+   |                           |  +-----+   |
        +------------+                           +------------+

            where (A), (B), (C) and (D) are reference points

                             Figure 4
```

   For devices with only local knowledge, one row is required on each
   device as follows:

   (A) frsldPvcCtrlTransmitRP for Device 1 = ingTxLocalRP(2)

   (B) frsldPvcCtlrReceiveRP for Device 2 = eqiRxLocalRP(4)

   (C) frsldPvcCtrlTransmitRP for Device 2 = ingTxLocalRP(2)

   (D) frsldPvcCtlrReceiveRP for Device 1 = eqiRxLocalRP(4)

   In which a single row is created on Device 1 containing reference
   points (A) and (D), and a single row is created on Device 2
   containing reference points (C) and (B).

For devices with both local and remote knowledge, the two rows can
exist in any combination on either device. For this example, the
transmitting devices will be responsible for information regarding
the flow for which they are the origin. Only one row is required per
device for this example.

(A) frsldPvcCtrlTransmitRP for Device 1 = ingTxLocalRP(2)

(B) frsldPvcCtlrReceiveRP for Device 1 = eqiRxRemoteRP(10)

(C) frsldPvcCtrlTransmitRP for Device 2 = ingTxLocalRP(2)

(D) frsldPvcCtlrReceiveRP for Device 2 = eqiRxRemoteRP(10)

3.6.2.1.3. End-to-End Using Reference Point Example

```
          Device 1                            Device 2
       +------------+                     +------------+
       |  Source    |                     |Destination |
       | +-----+    |                     |  +-----+   |
       |(A)|   |    |   Traffic Flow      |  |   |(B)|
    -->-->--    -->-->-->-->-->-->-->-->-->-   -->-->-->
       |   |    |   | From Device 1 to 2  |  |   |   |
       |   +-----+  |                     |  +-----+   |
       |            |                     |            |
       |Destination |                     |  Source    |
       | +-----+    |                     |  +-----+   |
       |(D)|   |    |   Traffic Flow      |  |   |(C)|
    <--<--<-    -<--<--<--<--<--<--<--<--<--   --<--<--
       |   |    |   | From Device 2 to 1  |  |   |   |
       |   +-----+  |                     |  +-----+   |
       +------------+                     +------------+
```

          where (A), (B), (C) and (D) are reference points

                            Figure 5

For devices with only local knowledge, one row is required on each
device as follows:

(A) frsldPvcCtrlTransmitRP for Device 1 = srcLocalRP(1)

(B) frsldPvcCtlrReceiveRP for Device 2 = desLocalRP(1)

(C) frsldPvcCtrlTransmitRP for Device 2 = srcLocalRP(1)

(D) frsldPvcCtlrReceiveRP for Device 1 = desLocalRP(1)

In which a single row is created on Device 1 containing reference
points (A) and (D), and a single row is created on Device 2
containing reference points (C) and (B).

For devices with both local and remote knowledge, the two rows can
exist in any combination on either device. For this example, the
transmitting devices will be responsible for information regarding
the flow for which they are the origin. Only one row is required per
device for this example.

(A) frsldPvcCtrlTransmitRP for Device 1 = srcLocalRP(1)

(B) frsldPvcCtlrReceiveRP for Device 1 = desRemoteRP(7)

(C) frsldPvcCtrlTransmitRP for Device 2 = srcLocalRP(1)

(D) frsldPvcCtlrReceiveRP for Device 2 = desRemoteRP(7)

3.6.3. Creation Process

In some cases, devices will automatically populate the rows of PVC
Control Table and potentially the Sample Control Table. However, in
many cases, it may be necessary for a network manager to manually
create rows.

Manual creation of rows requires the following steps:

1) Ensure the PVC exists between the two devices.

2) Determine the necessary reference points for row creation.

3) Create the row(s) in each device as needed.

4) Create the row(s) in the sample control tables if desired.

3.6.4. Destruction Process

3.6.4.1. Manual Row Destruction

Manual row destruction is straight forward. Any row can be destroyed
and the resources allocated to it are freed by setting the value of
its status object (either frsldPvcCtrlStatus or frsldSmplCtrlStatus)
to destroy(6). It should be noted that when frsldPvcCtrlStatus is
set to destroy(6) all associated sample control, sample and data
table rows will also be destroyed. Similarly, when
frsldSmplCtrlStatus is set to destroy(6) all sample rows will also be

destroyed. The frsldPvcCtrlPurge objects do not apply to manual row
destruction. If the row is set to destroy(6) manually, the rows are
destroyed as part of the set.

3.6.4.2. Automatic Row Destruction

Rows is the tables may be destroyed automatically based on the
existence of the DLCI on which they rely. This behavior is
controlled by the frsldPvcCtrlPurge and frsldPvcCtrlDeleteOnPurge
objects. When a DLCI no longer exists in the device, the data in the
tables has no relation to anything known on the network. However,
there may be some need to keep the historic information active for a
short period after the destruction or removal of a DLCI. If the
basis for the row no longer exists, the row will be destroyed at the
end of the purge interval that is controlled by frsldPvcCtrlPurge.

The effects of automatic row destruction are the same as manual row
destruction.

3.6.5. Modification Process

All read-create items in this MIB module can be modified at any time
if they are fully supported. Write access is not required. To
simplify the use of the MIB frsldPvcCtrlWriteCaps and
frsldSmplCtrlWriteCaps state which of the read-create variables can
actually be written on a particular device.

3.6.6. Collection Process

3.6.6.1. Remote Polling

This MIB module supports data collection through remote polling of
the free running counters in the PVC Data Table. Remote polling is a
common method used to capture real-time statistics. A remote
management station polls the device to collect the desired
information. It is recommended all statistics for a single PVC be
collected in a single PDU.

The following objects are designed around the concept of real-time
polling:

o   frsldPvcDataMissedPolls
o   frsldPvcDataFrDeliveredC
o   frsldPvcDataFrDeliveredE
o   frsldPvcDataFrOfferedC
o   frsldPvcDataFrOfferedE
o   frsldPvcDataDataDeliveredC
o   frsldPvcDataDataDeliveredE

    o frsldPvcDataDataOfferedC
    o frsldPvcDataDataOfferedE
    o frsldPvcDataHCFrDeliveredC
    o frsldPvcDataHCFrDeliveredE
    o frsldPvcDataHCFrOfferedC
    o frsldPvcDataHCFrOfferedE
    o frsldPvcDataHCDataDeliveredC
    o frsldPvcDataHCDataDeliveredE
    o frsldPvcDataHCDataOfferedC
    o frsldPvcDataHCDataOfferedE
    o frsldPvcDataUnavailableTime
    o frsldPvcDataUnavailables

3.6.6.2. Sampling

   The sample tables provide the ability to historically sample data
   without requiring the additional overhead of polling. At key
   periods, a network management station can collect the samples needed.
   This method allows the manager to perform the collection of data at
   times that will least affect the active network traffic.

   The sample data can be collected using a series of SNMP getNext or
   getBulk operations. The value of frsldPvcSmplIdx increments with
   each new collection bucket. This allows the managers to skip
   information that has already been collected. However, care should be
   taken in that the value can roll over after a long period of time.

   The start and end times of a collection period allow the manager to
   know what the actual period of collection was. It is possible for
   there to be discontinuities in the sample table, so both start and
   end should be referenced.

3.6.6.3. User History

   User history, as defined in RFC 2021 [19], is an alternative
   mechanism that can be used to get the same benefits as the sample
   table by using the objects provided for real-time polling. Some
   devices MAY have the ability to use user history and opt not to
   support the sample tables. If this is the case, the information from
   the data table can be used to define a group of user history objects.

3.6.7. Use of MIB Module in Calculation of Service Level Definitions

   The objects in this MIB module can be used to calculate the
   statistics defined in FRF.13 [17]. The description below describes
   the calculations for one direction of the data flow, i.e., data sent
   from local transmitter to a remote receiver. A complete set of
   bidirectional information would require calculations based on both

directions. For the purposes of this description, the reference
points used SHOULD consistently represent data that is sent by one
device and received by the other.

A complete evaluation requires the combination of two uni-directional
flows. It is possible for a management station to combine all of the
calculated information into one conceptual row. Doing this requires
that each of the metrics are collected for both flow directions and
grouped by direction If the information is split between two
devices, the management station must know which two devices to
communicate with for the collection of all information. The grouping
of information SHOULD be from ingress to egress in each flow
direction.

The calculations below use the following terminology:

o DelayAvg

       The average delay on the PVC. This is represented within the
       MIB module by frsldPvcSmplDelayAvg.

o FrDeliveredC

       The number of frames received by the receiving device through
       the receive reference point that were delivered within CIR.
       This is represented within the MIB module by one of
       frsldPvcDataFrDeliveredC, frsldPvcDataHCFrDeliveredC,
       frsldPvcSmplFrDeliveredC, or frsldPvcSmplHCFrDeliveredC.

o FrDeliveredE

       The number of frames received by the receiving device through
       the receive reference point that were delivered in excess of
       CIR. This is represented within the MIB module by one of
       frsldPvcDataFrDeliveredE, frsldPvcDataHCFrDeliveredE,
       frsldPvcSmplFrDeliveredE, or frsldPvcSmplHCFrDeliveredE.

o FrOfferedC

       The number of frames offered by the transmitting device through
       the transmit reference point that were sent within CIR. This
       is represented within the MIB module by one of
       frsldPvcDataFrOfferedC, frsldPvcDataHCFrOfferedC,
       frsldPvcSmplFrOfferedC, or frsldPvcSmplHCFrOfferedC.

   o FrOfferedE

      The number of frames offered by the transmitting device through
      the transmit reference point that were sent in excess of CIR.
      This is represented within the MIB module by one of
      frsldPvcDataFrOfferedE, frsldPvcDataHCFrOfferedE,
      frsldPvcSmplFrOfferedE, or frsldPvcSmplHCFrOfferedE.

   o DataDeliveredC

      The number of octets received by the receiving device through
      the receive reference point that were delivered within CIR.
      This is represented within the MIB module by one of
      frsldPvcDataDataDeliveredC, frsldPvcDataHCDataDeliveredC,
      frsldPvcSmplDataDeliveredC, or frsldPvcSmplHCDataDeliveredC.

   o DataDeliveredE

      The number of octets received by the receiving device through
      the receive reference point that were delivered in excess of
      CIR. This is represented within the MIB module by one of
      frsldPvcDataDataDeliveredE, frsldPvcDataHCDataDeliveredE,
      frsldPvcSmplDataDeliveredE, or frsldPvcSmplHCDataDeliveredE.

   o DataOfferedC

      The number of octets offered by the transmitting device through
      the transmit reference point that were sent within CIR. This
      is represented within the MIB module by one of
      frsldPvcDataDataOfferedC, frsldPvcDataHCDataOfferedC,
      frsldPvcSmplDataOfferedC, or frsldPvcSmplHCDataOfferedC.

   o DataOfferedE

      The number of octets offered by the transmitting device through
      the transmit reference point that were sent in excess of CIR.
      This is represented within the MIB module by one of
      frsldPvcDataDataOfferedE, frsldPvcDataHCDataOfferedE,
      frsldPvcSmplDataOfferedE, or frsldPvcSmplHCDataOfferedE.

   o UnavailableTime

      The amount of time the PVC was not available during the
      interval of interest. This is represented within the MIB
      module by either frsldPvcDataUnavailableTime or
      frsldPvcSmplUnavailableTime.

     o Unavailables

          The number of times the PVC was declared to be unavailable
          during the interval of interest. This is represented within
          the MIB module by either frsldPvcDataUnavailables or
          frsldPvcSmplUnavailables.

3.6.8. Delay

   The frame transfer delay is defined as the amount of time elapsed, in
   microseconds, from the time a frame exits the source to the time it
   reaches the destination. The average delay can be found using the
   MIB variable described in DelayAvg above. The delay may be
   calculated as either round trip or one way, and this information is
   held in the frsldPvcCtrlDelayType MIB variable. If the delay be
   calculated as round trip, the value of DelayAvg represents the
   average of the total delays of the round trips. In this case, the
   manager SHOULD divide the value returned by the agent by two to
   obtain the frame transfer delay. In the case that
   frsldPvcCtrlDelayType is oneWay, the value of DelayAvg represents the
   average of the frame transfer delays and SHOULD be used as is.

3.6.9. Frame Delivery Ratio

   The frame delivery ratio is defined as the total number of frames
   delivered to the destination divided by the frames offered by the
   source. The destination values can be obtained using FrDeliveredC
   and FrDeliveredE. The source values can be obtained using FrOfferedC
   and FrOfferedE.

$$Frame\ Delivery\ Ratio = \frac{FrDeliveredC + FrDeliveredE}{FrOfferedC + FrOfferedE}$$

$$Committed\ Frame\ Delivery\ Ratio = \frac{FrDeliveredC}{FrOfferedC}$$

$$Excess\ Frame\ Delivery\ Ratio = \frac{FrDeliveredE}{FrOfferedE}$$

3.6.10. Data Delivery Ratio

   The data delivery ratio is defined as the total amount of data
   delivered to the destination divided by the data offered by the
   source. The destination values can be obtained using DataDeliveredC
   and DataDeliveredE. The source values can be obtained using
   DataOfferedC and DataOfferedE.

$$\text{Data Delivery Ratio} = \frac{\text{DataDeliveredC} + \text{DataDeliveredE}}{\text{DataOfferedC} + \text{DataOfferedE}}$$

$$\text{Committed Data Delivery Ratio} = \frac{\text{DataDeliveredC}}{\text{DataOfferedC}}$$

$$\text{Excess Data Delivery Ratio} = \frac{\text{DataDeliveredE}}{\text{DataOfferedE}}$$

3.6.11. Service Availability

   Some forms of service availability measurement defined in FRF.13 [17]
   require knowledge of the amount of time the network is allowed to be
   unavailable during the period of measurement. This is called the
   excluded outage time and will be represented in the measurements
   below as ExcludedTime. It is assumed that the management software
   will maintain this information in that it often relates to specific
   times and dates that many devices are not capable of maintaining.
   Further, it may change based on a moving maintenance window that the
   device cannot track well.

   Mean Time to Repair (FRMTTR) = 0 if Unavailables is 0.

$$\text{Otherwise, FRMTTR} = \frac{\text{UnavailableTime}}{\text{Unavailables}}$$

   Virtual Connection Availability (FRVCA) = 0 if IntervalTime equals
                                             ExcludedTime.

$$\text{Otherwise, FRVCA} = \frac{\text{IntervalTime} - \text{ExcludedTime} - \text{UnavailableTime}}{\text{IntervalTime} - \text{ExcludedTime}} *100$$

   Mean Time Between Service Outages (FRMTBSO) = 0 if Unavailables is 0.

       Otherwise, FRMTBSO = IntervalTime - ExcludedTime - UnavailableTime
                            ----
                                            Unavailables

4. Relation to Other MIB Modules

   There is no explicit relation to any other frame relay MIB module nor
   are any required to implement this MIB module. However, there is a
   need for knowledge of ifIndexes and some understanding of DLCIs. The
   ifIndex information can be found in the IF-MIB [21] which is
   required. The DLCI information can be found in either the Frame
   Relay DTE MIB (RFC 2115) [20] or the Frame Relay Network Services MIB
   (RFC 2954) [18]; however, neither is required.

   Upon setting of frsldPvcCtrlStatus in the frsldPvcCtrlTable to
   active(1) the system can be in one of the following three states:

   (1) The respective DLCI is known and is active. This corresponds to
       a state in which frPVCEndptRowStatus is active(1) and
       frPVCEndptRcvdSigStatus is either active(2) or none(4) for the
       Frame Relay Network Services MIB (RFC 2954) [18]. For the Frame
       Relay DTE MIB, the same state is shown by frCircuitRowStatus of
       active(1) and frCircuitState of active(2).

   (2) The respective DLCI has not been created. This corresponds to a
       state in which the row with either frPVCEndptDLCIIndex or
       frCircuitDlci equal to the respective DLCI does not exist in
       either the frPVCEndptTable or the frCircuitTable respectively.

   (3) The respective DLCI has just been removed. This corresponds to a
       state in which either frPVCEndptRowStatus is no longer active(1)
       or frPVCEndptRcvdSigStatus is no longer active(2) or none(4) for
       the Frame Relay Network Services MIB (RFC 2954) [18]. For the
       Frame Relay DTE MIB, the same state is shown when either
       frCircuitRowStatus is no longer active(1) or frCircuitState is no
       longer active(2).

   For the first case, the row in the frsldPvcDataTable will be filled.
   If frsldSmplCtrlStatus in the frsldSmplCtrlTable for the respective
   DLCI is also 'active' the frsldPvcSampleTable will be filled as well.

   For the second case, the respective rows will not be added to any of
   the data or sample tables and frsldPvcCtrlStatus SHOULD report
   notReady(3).

   For the third case, frsldPvcCtrlDeleteOnPurge should direct the
   behavior of the system. If all tables are purged, this case will be
   equivalent to the second case above. Otherwise, frsldPvcCtrlStatus
   SHOULD remain active(1).

5. Structure of the MIB Module

   The FRSLD-MIB consists of the following components:

   o frsldPvcCtrlTable

   o frsldSmplCtrlTable

   o frsldPvcDataTable

   o frsldPvcSampleTable

   o frsldCapabilities

   Refer to the compliance statement defined within for a definition of
   what objects MUST be implemented.

5.1. frsldPvcCtrlTable

   The frsldPvcCtrlTable is the central control table for operations of
   the Frame Relay Service Level Definitions MIB. It provides variables
   to control the parameters required to calculate the objects in the
   other tables.

   A row in this table MUST exist in order for a row to exist in any
   other table in this MIB module.

5.2. frsldSmplCtrlTable

   This is an optional table to allow control of sampling of the data in
   the data table.

5.3. frsldPvcDataTable

   This table contains the calculated data. It relies on configuration
   from the control table.

5.4. frsldPvcSampleTable

   This table contains samples of the delivery and availability
   information from the data table as well as delay information
   calculated over the sample period. It relies on configuration from
   both the control table and the sample control table.

5.5. frsldCapabilities

   This is a group of objects that define write capabilities of the
   read-create objects in the tables above.

6. Persistence of Data

   The data in frsldPvcCtrlTable and frsldSmplCtrlTable SHOULD persist
   through power cycles. Note, however, that the symantics of readiness
   for the rows still applies. This means that it is possible for a row
   to be reprovisioned as notReady(3) if the underlying DLCI does not
   persist. The data collected in the other tables SHOULD NOT persist
   through power cycles in that the reference TimeStamp is no longer
   valid.

7. Object Definitions

FRSLD-MIB DEFINITIONS ::= BEGIN

    DESCRIPTION
        "The MIB module to describe generic objects for
         FRF.13 Frame Relay Service Level Definitions."
    REVISION "200201030000Z" -- January 3, 2002
    DESCRIPTION
        "Initial version, published as RFC 3202"
    ::= { mib-2 95 }

--
-- Textual Conventions
--
FrsldTxRP ::= TEXTUAL-CONVENTION
    STATUS   current
    DESCRIPTION
        "The reference point a PVC uses for calculation
         of transmitter related statistics.

         The valid values for this type of object are as follows:
            - srcLocalRP(1) for the local source
            - ingTxLocalRP(2) for the local ingress queue input
            - tpTxLocalRP(3) for the local traffic policing
            - eqiTxLocalRP(4) for the local egress queue input
            - eqoTxLocalRP(5) for the local egress queue output
            - otherTxLocalRP(6) for any other local transmit point
            - srcRemoteRP(7) for the remote source
            - ingTxLocalRP(8) for the remote ingress queue input
            - tpTxLocalRP(9) for the remote traffic policing
            - eqiTxRemoteRP(10) for the remote egress queue input

        STATUS       current
```

        DESCRIPTION
            "The status of the current row. This object is
             used to add, delete, and disable rows in this
             table. When the status changes to active(1) for the
             first time, a row will also be added to the data
             table below. This row SHOULD not be removed until
             the status is changed to deleted.

             When this object is set to destroy(6), all associated
             sample and data table rows will also be deleted.
             When this object is changed from active(1) to any
             other valid value, the defined purge behavior will
             affect the data and sample tables.

             The rows added to this table MUST have a valid
             ifIndex and an ifType related to frame relay. Further,
             the reference points referred to by frsldPvcCtrlTransmitRP
             and frsldPvcCtrlReceiveRP MUST be supported (see the
             frsldRPCaps object).

             If at any point the row is not in the active(1) state
             and the DLCI no longer exists, the state SHOULD
             report notReady(3).

             The data in this table SHOULD persist through power
             cycles. The symantics of readiness for the rows still
             applies. This means that it is possible for a row to be
             reprovisioned as notReady(3) if the underlying DLCI does
             not persist."

8. Acknowledgments

   This document was produced by the Frame Relay Service MIB Working
   Group. It is based on the Frame Relay Forum's implementation
   agreement on service level definitions, FRF.13 [17].

   The editors would like to thank the following people for their
   helpful comments:

   o Ken Rehbehn, Visual Networks

   o Santa Dasu, Quick Eagle Networks

10. Security Considerations

   There are a number of management objects defined in this MIB that
   have a MAX-ACCESS clause of read-write and/or read-create. Such
   objects may be considered sensitive or vulnerable in some network
   environments. The support for SET operations in a non-secure
   environment without proper protection can have a negative effect on
   network operations.

   SNMPv1 by itself is not a secure environment. Even if the network
   itself is secure (for example by using IPSec), even then, there is no
   control as to who on the secure network is allowed to access and
   GET/SET (read/change/create/delete) the objects in this MIB.

   It is recommended that the implementers consider the security
   features as provided by the SNMPv3 framework. Specifically, the use
   of the User-based Security Model RFC 2574 [12] and the View-based
   Access Control Model RFC 2575 [15] is recommended.

   It is then a customer/user responsibility to ensure that the SNMP
   entity giving access to an instance of this MIB, is properly
   configured to give access to the objects only to those principals
   (users) that have legitimate rights to indeed GET or SET
   (change/create/delete) them.
